

Let the sequence S consist of s_1, \dots, s_n and the sequence S' consist of s'_1, \dots, s'_m . We give a greedy algorithm that finds the first event in S that is the same as s'_1 , matches these two events, then finds the first event after this that is the same as s'_2 , and so on. We will use k_1, k_2, \dots to denote the match have we found so far, i to denote the current position in S , and j the current position in S' .

```

Initially  $i = j = 1$ 
While  $i \leq n$  and  $j \leq m$ 
    If  $s_i$  is the same as  $s'_j$ , then
        let  $k_j = i$ 
        let  $i = i + 1$  and  $j = j + 1$ 
    otherwise let  $i = i + 1$ 
EndWhile
If  $j = m + 1$  return the subsequence found:  $k_1, \dots, k_m$ 
Else return that " $S'$  is not a subsequence of  $S$ "

```

The running time is $O(n)$: one iteration through the while loop takes $O(1)$ time, and each iteration increments i , so there can be at most n iterations.

It is also clear that the algorithm finds a correct match if it finds anything. It is harder to show that if the algorithm fails to find a match, then no match exists. Assume that S' is the same as the subsequence s_{l_1}, \dots, s_{l_m} of S . We prove by induction that the algorithm will succeed in finding a match and will have $k_j \leq l_j$ for all $j = 1, \dots, m$. This is analogous to the proof in class that the greedy algorithm finds the optimal solution for the interval scheduling problem: we prove that the greedy algorithm is always ahead.

- For each $j = 1, \dots, m$ the algorithm finds a match k_j and has $k_j \leq l_j$.

Proof. The proof is by induction on j . First consider $j = 1$. The algorithm lets k_1 be the first event that is the same as s'_1 , so we must have that $k_1 \leq l_1$.

Now consider a case when $j > 1$. Assume that $j - 1 < m$ and assume by the induction hypothesis that the algorithm found the match k_{j-1} and has $k_{j-1} \leq l_{j-1}$. The algorithm lets k_j be the first event after k_{j-1} that is the same as s'_j if such an event exists. We know that l_j is such an event and $l_j > l_{j-1} \geq k_{j-1}$. So $s_{l_j} = s'_j$, and $l_j > k_{j-1}$. The algorithm finds the first such index, so we get that $k_j \leq l_j$. ■
