

Clearly if any of the putative degrees  $d_i$  is equal to 0, then this must be an isolated node in the graph; thus we can delete  $d_i$  from the list and continue by recursion on the smaller instance.

Otherwise, all  $d_i$  are positive. We sort the numbers, relabeling as necessary, so that  $d_1 \geq d_2 \geq \dots \geq d_n > 0$ . We now look at the list of numbers

$$L = \{d_1 - 1, d_2 - 1, \dots, d_{d_n} - 1, d_{d_n+1}, \dots, d_{n-2}, d_{n-1}\}.$$

(In other words, we subtract 1 from the first  $d_n$  numbers, and drop the last number.) We claim that there exists a graph whose degrees are equal to the list  $d_1, \dots, d_n$  if and only if there exists a graph whose degrees form the list  $L$ . Assuming this claim, we can proceed recursively.

Why is the claim true? First, if there is a graph with degree sequence  $L$ , then we can add an  $n^{\text{th}}$  node with neighbors equal to nodes  $v_1, v_2, \dots, v_{d_n}$ , thereby obtaining a graph with degree sequence  $d_1, \dots, d_n$ . Conversely, suppose there is a graph with degree sequence  $d_1, \dots, d_n$ , where again we have  $d_1 \geq d_2 \geq \dots \geq d_n$ . We must show that in this case, there is in fact such a graph where node  $v_n$  is joined to precisely the nodes  $v_1, v_2, \dots, v_{d_n}$ ; this will allow us to delete node  $n$  and obtain the list  $L$ . So consider any graph  $G$  with degree sequence  $d_1, \dots, d_n$ ; we show how to transform  $G$  into a graph where  $v_n$  is joined to  $v_1, v_2, \dots, v_{d_n}$ . If this property does not already hold, then there exist  $i < j$  so that  $v_n$  is joined to  $v_j$  but not  $v_i$ . Since  $d_i \geq d_j$ , it follows that there must be some  $v_k$  not equal to any of  $v_i, v_j, v_n$  with the property that  $(v_i, v_k)$  is an edge but  $(v_j, v_k)$  is not. We now replace these two edges by  $(v_i, v_n)$  and  $(v_j, v_k)$ . This keeps all degrees the same; and repeating this transformation will convert  $G$  into a graph with the desired property.
